Jan 28, 2013 It is a good news to know you have a first degree burn that can be used to recover your files. Endothelial procoagulant activity in diseased and normal human coronary arteries. Thrombin activates endothelial cells, resulting in the release of procoagulant material, and may also have vasoactive properties. We hypothesized that endothelial tissue factor (TF) activity may be increased in atherosclerotic human coronary arteries, and that clotting times in ex vivo perfusion are faster in coronary arteries of patients with coronary artery disease (CAD) than in controls. Endothelial cells were collected from normal (n=12) and diseased coronary arteries (n=14) from elective patients undergoing coronary artery

bypass grafting. Cells were incubated in calcium (5.5 microM) with 1 IU/mL of thrombin for 0-240 min. Media were collected and activity was assayed by measuring prothrombin activation and activation of purified FVII (Factor VII) in presence of purified FV (Factor V), phospholipids, and Ca(2+) in the absence or presence of tissue factor (TF) pathway inhibitors. Activity of prothrombin activation was inhibited by phospholipase A(2) and proteinase inhibitors, and reduced significantly in diseased arteries. Inhibition of TF or Factor X (FX) significantly increased activity in both groups. There were no significant changes in FVII activation by TF/FVII complexes in either group. However, in diseased arteries activation of FVII by both TF/FVII and

prothrombin was faster in the presence of tissue factor pathway inhibitor (TFPI) compared to the control, and was attributed to the addition of TFPI. These results suggest that thrombin-induced procoagulant activity is increased in the arterial endothelium of patients with CAD. { [pool release]; break; } } } // Set the sprite frame using the file name from the originator theSprite.content = [NSString f678ea9f9e
